

# SIMATS ENGINEERING ASSESSMENT TOOLS

COURSE NAME: Theory of Computation

COURSE CODE: CSA13

---

## COURSE OUTCOME COVERED

CO4: Construct Context-Free Grammars, generate derivations and parse trees to demonstrate the syntactic structure of strings. (BL : 3)

Assessment Tool Weightage: 20%

---

QUESTIONS: 5  
Duration : 1 Hour

Total Marks:25

Industry Problem

---

Code of Conduct:

I A-Manoj Reddy 1a2311171 (Name / Reg No) certify that this submission is my original work and that I have adhered to the guidelines specified for this assessment.

I understand that any violation of academic integrity rules will result in disciplinary action.

Signature of the student:

# SIMATS ENGINEERING ASSESSMENT TOOLS

1. Design and implement a **C-based validation module** that simulates a **Deterministic Finite Automaton (DFA)** to verify input strings in a real-time system. The module should accept only those strings that **begin with the character 'a' and end with the character 'a'**, ensuring compliance with predefined input format rules (e.g., protocol validation, pattern filtering, or secure data transmission).

The system should:

- Process user input dynamically
- Validate strings based on DFA state transitions
- Output whether the given input is **Accepted** or **Rejected**

2. Design a Push Down Automata that accepts the language

$$L = \{w \mid w \in (0 + 1)^* \text{ and } n_0(w) = n_1(w)\}$$

$n_0(w)$  is the number of 0's in  $w$

$n_1(w)$  is the number of 1's in  $w$

3. Design a Pushdown Automata for the language representing a's followed by b's and the number of b's must be twice that of a's.

$$L = \{a^n b^{2n} \mid n \geq 1\}$$

4. Develop a **C-based computational module** to determine the  **$\epsilon$ -closure of all states** in a **Non-Deterministic Finite Automaton (NFA) with  $\epsilon$ -transitions**, as part of an automata processing engine used in compiler construction and pattern-matching systems.

5. Develop a **C-based input validation module** that determines whether a given binary string conforms to a specified **Context-Free Grammar (CFG)** used in structured data validation systems.

The grammar is defined as:

- $S \rightarrow 0 A 1$
- $A \rightarrow 0 A \mid 1 A \mid \epsilon$

C program to simulate a DFA for strings that begin with a and end with a.

### DFA states:

- $q_0$  = initial state
- $q_1$  = string started with a and currently ends with a
- $q_2$  = string started with a and currently ends with another symbol
- $q_d$  = dead state

Assuming the alphabet is  $\{a, b\}$ :

| Present state | Input a | Input b |
|---------------|---------|---------|
| $q_0$         | $q_1$   | $q_d$   |
| $q_1$         | $q_1$   | $q_2$   |
| $q_2$         | $q_1$   | $q_2$   |
| $q_d$         | $q_d$   | $q_d$   |

### C program:-

```
#include <stdio.h>
```

```
#include <string.h>
```

```
int main()
```

```
{ char str[100];
```

```
  int state = 0;
```

```
  printf("Enter the string:");
```

```
  scanf("%s", str);
```

```
for (int i=0; i < strlen(str); i++)
```

```
{
```

```
    switch (state)
```

```
{
```

```
    case 0:
```

```
        if (str[i] == 'a')
```

```
            state = 1;
```

```
        else
```

```
            state = 3;
```

```
        break;
```

```
    case 1:
```

```
        if (str[i] == 'a')
```

```
            state = 1;
```

```
        else if (str[i] == 'b')
```

```
            state = 2;
```

```
        else
```

```
            state = 3;
```

```
        break;
```

```
    case 2:
```

```
        if (str[i] == 'a')
```

```
            state = 1;
```

```
        else if (str[i] == 'b')
```

```
            state = 2;
```

```
        else
```

```
            state = 3;
```

```
        break;
```

```
    }
```

```
}
```

```
if (state == 1)
```

```
    printf (" Accepted \n");
```

```
else:
```

```
    printf (" Rejected \n");
```

```
    return 0;
```

```
}
```

Input: abba

Output: Accepted

Input: abb

Output: Rejected.

PDA for equal number of 0's and 1's

The language given in the question is

$$L = \{ w \mid w \in (0+1)^* \text{ and } n_0(w) = n_1(w) \}$$

Idea:-

Use the stack to keep track of the unmatched symbols

- if 0 is read and stack top contains 1, pop it
- otherwise push 0.
- if 1 is read and the stack top contains 0, pop it.
- other wise push 1
- Accept when the complete input is processed and only the bottom stack symbol remains.

let :

$$M = (\{q_0, q_f\}, \{0, 1\}, \{0, 1, z_0\}, \delta, (q_0, z_0, q_f))$$

transitions.

$$\delta(10, 0, z_0) = (q_0, 0z_0)$$

$$\delta(q_0, 1, z_0) = (q_0, 1z_0)$$

$$\delta(10, 0, 0) = (q_0, 00)$$

$$\delta(q_0, 1, 1) = (q_0, 11)$$

when opposite symbols occur:

$$\delta(q_0, 0, 1) = (q_0, \epsilon)$$

$$\delta(q_0, 1, 0) = (q_0, \epsilon)$$

finally  $\delta(q_0, \epsilon, z_0) = (q_f, z_0)$

Example:

for

$$w = 0101$$

Stack processing!

| Input | Stack      |
|-------|------------|
| 0     | 0          |
| 1     | $\epsilon$ |
| 0     | 0          |
| 1     | $\epsilon$ |

$$n_0(w) = 2, \quad n_1(w) = 2$$

Hence 0101 is Accepted.

PDA for  $L = \{ a^n b^{2n} \mid n \geq 1 \}$

examples:

abb

aabbbb

aaabbbbb

PDA Idea

for every a, push two stack symbols x

for every b, pop one x.

Therefore:

• 1 a  $\rightarrow$  2 x's

• 2 as  $\rightarrow$  4 x's

• 3 as  $\rightarrow$  6 x's

Accept when all input symbols are consumed and  
all x's are removed

$$M = ( \{q_0, q_1, q_f\}, \{a, b\}, \{x, z_0\}, \delta, q_0, z_0, \{q_f\} )$$

transition:-

for first a:

$$\delta(q_0, a, z_0) = (q_0, xxz_0)$$

for every additional a:

$$\delta(q_0, a, x) = (q_0, xxx)$$

this effectively adds two new x's.

4.

## $\epsilon$ - Closure of NFA

C program:-

```
#include <stdio.h>
```

```
int e[10][10], v[10], n;
```

```
void closure (int s) {
```

```
    v[s] = 1
```

```
    for (int i = 0; i < n; i++)
```

```
    {
```

```
        if (e[s][i] && !v[i])
```

```
            closure(i);
```

```
    }
```

```
int main() {
```

```
    int m, a, b;
```

```
    scanf ("%d %d", &n, &n);
```

```
    while (n-- > 0)
```

```
        scanf ("%d %d", &a, &b);
```

```
        e[a][b] = 1;
```

```
    }
```

```
    for (int s = 0; s < n; s++) {
```

```
        for (int i = 0; i < n; i++) v[i] = 0;
```

```
        closure (s);
```

```
        printf ("ε-closure (a %d) :- ", s);
```

```
        for (int i = 0; i < n; i++)
```

```
if (v[i] printf ("2 %.d", i);
```

```
printf ("ln");
```

```
}
```

```
return 0;
```

```
}
```

CFG validation:-

$S \rightarrow 0A1, A \rightarrow 0A|1A| \epsilon$

```
# include <stdio.h>
```

```
# include <string.h>
```

```
int main() {
```

```
    char s[100];
```

```
    scanf ("%s", s);
```

```
    int n = strlen(s);
```

```
    if (n == 2 & & s[0] == '0' & & s[n-1] == '1')
```

```
        printf ("Accepted");
```

```
    else
```

```
        printf ("Rejected");
```

```
    return 0;
```

```
}
```

Input 00101 → Accepted

1010 → Rejected.
